

Draft, not for submission: Evidence-Gated Exact English Palindrome Generation

Anonymous ACL submission

Abstract

The target of English palindrome generation is a long, exact, independently constructed text that people can read as English, not fast search or an automatic proxy. This draft reports no accepted system output. A provenance audit disqualified a character-crossing relexicalization ablation: its exact surfaces preserved the syntactic frame of a familiar catalogue palindrome. Independent code now recomputes every hard gate and rejects that entire family. The earlier reader package is withdrawn rather than used to make a readability claim. A future submission requires an independently constructed survivor and blinded human evidence.

1 Introduction

Let $n(x)$ lowercase a text and retain ASCII letters only. A rendered text x is an exact letter-level palindrome when

$$n(x) = \text{rev}(n(x)). \quad (1)$$

The equation permits ordinary punctuation but couples distant lexical choices character by character. Code must prove exactness; only blinded readers can establish grammaticality and coherence. We reject word-order reflection, self-palindromic building blocks, catalogue copying, punctuation-dependent changes, fragments, and word lists.

2 Rejected character-crossing ablation

The ablation realizes one dependency schema:

*SUBJECT lets RECIPIENT see
OWNER's telegram.*

The finite verb licenses a human object and a bare infinitive; the infinitive licenses a concrete possessed object. It enumerates typed names and accepts only literal normalized character palindromes. This is not an independent candidate generator: the frame is a relexicalization of a familiar published construction, so exact closure cannot promote a surface to an output.

Run	Exact closures	Accepted outputs
Catalogue-family ablation	4	0

Table 1: The provenance gate rejects every exact closure in the borrowed frame. Exactness alone is not candidate admission.

The frozen inventory contains 100 typed derivations. Four close exactly. The familiar control (National Institute of Environmental Health Sciences, 2026) and its name-substituted surfaces all preserve the same borrowed frame. The provenance gate consequently rejects every closure, including surfaces absent from a local catalogue. This is a hard exclusion, not a novelty claim or a motivation to weaken the gate.

3 Independent verification

Every exact closure stores the rendering, normalized length, slots, dependency witness, reflected character spans, and gate results. The primary verifier uses the project normalizer. A separate standard-library verifier applies case folding, ASCII-letter regular-expression extraction, a reversed-string comparison, and independently reimplements each hard gate. It confirms that all four closures are exact and that none is promotion-eligible.

Exactness is not readability. A valid completion can still be a list of words without coherent meaning, and a dependency witness cannot substitute for a reader judgment. The rejected ablation uses finite Cartesian enumeration; a future independent constructor may use an outside-in character-remainder search, following Norvig (2016), but that method is not claimed as an implementation result here.

4 Blinded reader evaluation

There is no active reader study for this ablation. Its earlier 24-form package is withdrawn: it exposed matched variants of each event to the same rater, used stable condition-correlated opaque IDs, and did not provide a sufficient blind paraphrase-coding plan. A replacement study must use inaccessible keys, between-rater assignment of competing variants, counterbalanced order, blinded dual paraphrase coding, and independently generated candidate items. No reader responses have been collected or are claimed.

5 Conclusion and limitations

This ablation does not support a submission claim: it has no independently constructed output, no valid reader study, and no human-readability evidence. It is retained to enforce the provenance gate. The next manuscript must center an independent construction method, exact independent verification, rendered non-catalogue examples, and a corrected blinded human study.

A Reproduction

The release contains an ablation generator and a separately implemented standard-library verifier. Each refuses to overwrite an existing output. The verifier recomputes every gate rather than trusting the generator's stored checks. The archived reader-package builder refuses this rejected family.
